It can take four years, and up to *ca.* 4,000 antibodies to find a lead candidate. What if we could reduce this timeline and express only a fraction of these proteins?

The Innovation Cycle

Machine Learning (ML) and Artificial Intelligence (AI) are transforming scientific innovation

Scientific innovation process is an experimentally-driven Design-Make-Test-Analyze cycle. Its success rate is driven by making the best informed design decisions on 'what to make next?'

The wealth of historical experimental data available means that many biologically relevant end-points can be predicted *in silico* using machine learning. Potentially, new virtual entities can be designed and rapidly optimized, before being passed to the lab to be physically expressed and screened.

Optimization: Scoring and Ranking

Each member of a virtual generation is scored according to how closely the predicted properties meet the target product profile requirements.

Score is assessed either by:

- Multi-Objective Optimization (MOO) methods such as Pareto-based optimization
- or by transforming the MOO into a Single Objective Optimization (SOO) problem using approaches such as Weighted Sum or Derringer Desirability

Automated Molecular Optimization: Multi-Objective Progress

Predicting Properties Associated with the Target Product Profile

Using available experimental data, Machine Learning (ML) algorithms and molecular simulations are applied to generate predictive models.

- Use a set of models to assess each virtual library member relative to the target product profile
- Rapidly assess the suitability of each member of a virtual generation before physically making and testing
- Dynamic: Models are not static. As new experimental data is generated, models are retrained and updated

Sequence-based

- Molecular weight
- Isoelectric point
- Charge
- hydrophilicity & hydrophobicity

3D Structure-based

- Aggregation
- Developability Index
- Binding Affinity
- Mutation Energy

Molecule Name	Transformation
2FJF_LH_FAB_LH_FV210ASP	H.LEU111>ASP
2FJF_LH_FAB_LH_FV208GLU	H.PHE109>GLU
2FJF_LH_FAB_LH_FV53GLU	L.PHE66>GLU
2FJF_LH_FAB_LH_FV53LYS	L.PHE66>LYS

Calculate sequence-based Properties

mAb	Mutation	E (stability)	Effect	Solubility	Aggregation	Half-Life
1	L:Phe66>Glu	-0.06	Neutral	423	-522	Same
2	Phe66>Lys	0.32	Neutral	420	-523	Same
3	L:Wild	0	Neutral	407	-480	-
4	L:Ser56>Arg	0.56	Neutral	422	-555	Same

Generate Homology Models

Calculate Structure-based Properties

Automated Lead Optimization (ALO)

Improve the efficiency of the Design cycle:

- Rapidly generate and optimize new molecular entities against the full target product profile *in silico*, before submitting optimized leads to the lab
- Use latest lab results in active learning cycle to retrain Machine Learning models

Pruning and Evolving new Generations

At the end of each enumeration cycle, the virtual members are ranked and the most optimal entities of the population retained.

The optimization cycle ends if:

- The target product profile has been met
- The maximum number of iterations has been completed or
- No further improvement can be achieved

Otherwise, the top entities are used as starting points for a next virtual generation of new entities and optimization

Generative Lead Mutations

Each cycle begins with either experimental hits and leads, known drugs or the top members of a previous ALO cycle. From these sequences, novel virtual analogs are generated and can be either relatively similar or highly novel, depending on the level of desired diversity.
